## Computer Algorithms

### *String Matching & Computational Geometry*

24-25

D B Kulkarni

Information Technology Department

# Agenda

- Introduction string comparison
- Rabin Karp
-

# String Matching

Given Text  $T[1..n]$ , Pattern  $P[1..m]$  elements of  $T$  and  $P$  are drawn from  $\Sigma$  e.g.  $\Sigma=\{0,1\}$  or  $\Sigma=\{a,b,..z\}$

- Pattern  $P$  occurs with shift  $s$  in  $T$  (  $p$  occurs beginning at position  $s+1$  in text  $T$  ) if  $0 \leq s \leq (n-m)$  and  $T[s+1,s+2,...s+m]=P[1..m]$

# Terminology

- $\Sigma^*$  be set of all finite length strings formed using  $\Sigma$
- $\epsilon$ - be zero length empty string
- Length of string  $x$  is  $|x|$

Preceding (Prefix) and Following (suffix)

- ❖ String  $w$  is called a prefix of string  $s$  if  $s = wy$  for some string  $y$  in  $\Sigma^*$ . This is denoted  $w \sqsubseteq s$
- ❖ String  $w$  is a suffix of  $s$ , denoted  $w \sqsupseteq s$ , if  $s = yw$  for some  $y$  in  $\Sigma^*$ .
- Example,  $ax \sqsubseteq \text{axiometric}$  and  $\text{metric} \sqsupseteq \text{axiometric}$ .

- Overlapping suffix lemma  
Suppose  $x, y, z$  are strings such that  $x]z$  and  $y]z$  then

- If  $|x| \leq |y|$  then  $x]y$
- If  $|x| \geq |y|$  then  $y]x$
- If  $|x| = |y|$  then  $x = y$

## Rabin Karp

### Challenges

- Decide prime number

### Applications

- Plagiarism

- Multiple pattern matching

### Modified

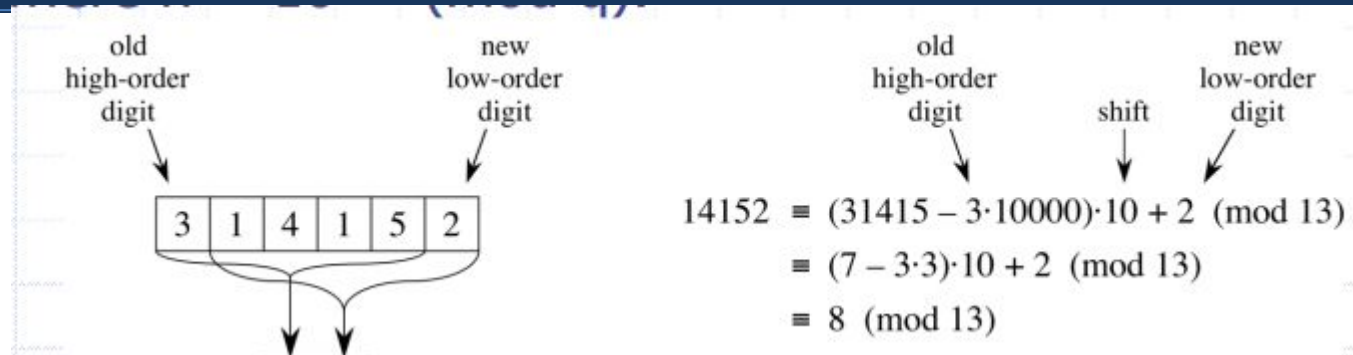

- Extend Rabin Karp for 2D pattern matching

  - $n \times n$  text with  $m \times m$  pattern

# Rabin-Karp Algorithm

Use mod function

- How will this technique be applicable for text characters?

Using Hashing technique

- Map characters to digit
- E.g. if  $\Sigma = \{a, b, c, d, e\}$  is mapped on to  $\{1, 2, 3, 4, 5\}$  then  
     $T = abecda = \{125341\}$  and  $P = cda = \{341\}$
- Use Hash function  $3^n$
- $P = cda \rightarrow \text{Hash} = 341 \sim 3 \times 3^0 + 4 \times 3^1 + 1 \times 3^2 = 24$
- Take abe part of  $T = \{125\} \rightarrow \text{Hash} = 52$  which is not equal to 24
- Take the next digit 3- $\{253\} \rightarrow \text{Hash} = (52-1)/3 + 3 \times 3^2 = 44$
- Take the next digit 4- $\{534\} \rightarrow \text{Hash} = (44-2)/3 + 4 \times 3^2 = 50$
- Take the next digit 1- $\{341\} \rightarrow \text{Hash} = (50-5)/3 + 1 \times 3^2 = 24$  Match after individual comparison

Find longest prefix which is proper suffix of P

# Knuth Morris Pratt (KMP) Algorithm

a	b	a	b	a	c	a
---	---	---	---	---	---	---

Find longest prefix which is proper suffix of P

Use auxiliary function  $\pi$ , which is precomputed from pattern

$\pi =$ 

0	0	1	2	3	0	1
---	---	---	---	---	---	---

# KMP

b	a	c	b	a	b	a	b	c	a	b	c	b	a	b
---	---	---	---	---	---	---	---	---	---	---	---	---	---	---

a	b	a	b	a	c	a
---	---	---	---	---	---	---

0	0	1	2	3	0	1
---	---	---	---	---	---	---

$k=4; \pi(3)=2$

Shift pattern by 2

Start matching

b	a	c	b	a	b	a	b	c	a	b	c	b	a	b
---	---	---	---	---	---	---	---	---	---	---	---	---	---	---

a	b	a	b	a	c	a
---	---	---	---	---	---	---

0	0	1	2	3	0	1
---	---	---	---	---	---	---

# Convex Polygon

- Definition: If we join any two point within polygon, all the points lying on the line are within the polygon.

- Check if point F is within polygon ABCDE

Problem statement: How will you form a convex polygon out of  $n$  given vertices?

- Vertices forming convex polygon,  $k$  where ( $k \ll n$ )
- Order in which these  $k$  points be connected

# Convex Polygon

- Given set of points ( $n$ - with  $x$  and  $y$  coordinates), find whether the polygon defined by  $n$  points is convex?
  - Order of points is important!
  - Find if the a given point is within the polygon....?

Given a line (AB) and a point C, decide to which side of the the line, the point lies?

Solution: Triangles that can be formed out of given  $n$  points  
 $O(n^3)$

- Check for every point, if it lies within any one of these triangles
- Assume that checking if point lies within triangle takes one unit
- There are  $n$  points, so total time  $O(n^4)$

# Divide and Conquer (D&C)

- Select extreme points (left, right)
- Line joining these points divides the space in lower/upper hull
- Upper Hull
  - Select triangle formed by these two points and third point where the area is max
  - Remove all points in this triangle
  - Consider two smaller hulls above the sides of triangle
  - Repeat till only one point left
- Repeat the process for lower Hull

# Upper hull

Complexity:  $n \log n$

## Other methods: Graham scan

- Note lowest and highest point
- Start from lowest point
- At every point search for point which makes lowest polar angle with +ve X axis
- Complexity  $n \cdot h$  ( $h$ - points defining convex polygon)

## Other methods: Jarvis march

- Start from lowest point
- Sort all points based on their increasing polar angles with +ve X axis
- Consider 3 successive points  $p_1, p_2, p_3$
- If  $p_3$  is to the left of  $P_1p_2$  include  $p_2$  in list of points defining CH
- Consider next point in order  $p_4$   
( $p_2p_3p_4$ )-> $p_1p_2p_3$
- Recurse
  
- Complexity  $n \log n$

# Closest pair of points algorithm

- Consider all possible pair of points
  - Take a point, calculate its distance from every other point
  - Do it for all points
- Compute the minimum distance
- Complexity:  $O(n^2)$

# Closest pair of points - Divide and Conquer

- Divide the plane vertically into Left ( $S_1$ ) and Right ( $S_2$ ) region
- Find the closest pair in  $S_1$  and  $S_2$  region
- Let  $\delta_1$  be distance of closest pair in  $S_1$  and  $\delta_2$  be distance of closest pair in  $S_2$
- Let  $\delta = \min(\delta_1, \delta_2)$

# Closest pair of points algorithm

# Pair of intersecting segments

- Intersecting (1)
- Non intersecting(2)
- Parallel (3)
- Colinear(overlap, 4)
- Colinear (5)

# Orientation

- Orientation of an ordered triplet of points in the plane can be
  - Counterclockwise
  - Clockwise
  - colinear
- The following diagram shows different possible orientations of (a, b, c)

Clockwise

Counterclockwise

Collinear

# Intersection

- Two segments  $(p_1, q_1)$  and  $(p_2, q_2)$  intersect if and only if one of the following two conditions is verified

## General Case:

- $(p_1, q_1, p_2)$  and  $(p_1, q_1, q_2)$  have different orientations  
and
- $(p_2, q_2, p_1)$  and  $(p_2, q_2, q_1)$  have different orientations.

## Special case:—

- $(p_1, q_1, p_2)$ ,  $(p_1, q_1, q_2)$ ,  $(p_2, q_2, p_1)$ , and  $(p_2, q_2, q_1)$  are all collinear  
and
- the x-projections of  $(p_1, q_1)$  and  $(p_2, q_2)$  intersect
- the y-projections of  $(p_1, q_1)$  and  $(p_2, q_2)$  intersect

# Intersection of line-segments

- Bruteforce method
  - For every segment
    - Check if it intersects with remaining others
- Complexity
  - $n(n-1)/2$
- Sweepline
  - Scans from L-R
  - Generates event
    - Insert
    - Delete
    - Intersect

# Whether pair of segments intersect?
